

ABSTRACT OF THE DISCLOSURE

The invention relates to a door device with at least one door, for opening and closing a passageway, such as used in stores, public buildings, or similar.

The doors may be displaced in a door frame, for example, by means of a
5 rotational or longitudinal displaceable mounting. The door device is further provided with at least one air curtain device, essentially running along the complete height of the passageway and which generates an exiting air curtain, such that, with the door open, the passageway is screened by the air curtain.

The generated air curtain serves to reduce the energy losses which occur when
10 air from the outside of the door device reaches the inside of the door device, or vice versa. According to the invention, a door device may be achieved which not only permits the access of people and objects, but also identification of the people, objects, or similar and the management thereof is as uncomplicated as possible, whereby the door device is provided with at least one additional
15 identification system. The identification system includes at least one sensor unit, a control unit and an output unit which are connected to each other.

Furthermore, at least one sensor unit in the identification system is integrated in the air curtain device.
